1 **GOLF CLUB SWING ANALYZERS AND GOLF SWING ANALYSIS**
2 **METHODS**

3 **CROSS REFERENCE TO RELATED APPLICATIONS**

4 This application claims priority from U.S. Provisional Application
5 Serial No. 60/083,892, filed May 1, 1998, titled "Indoor-Outdoor Sensor
6 System for Golf Swing Analyzers", naming Charles H. Blankenship as
7 inventor, and incorporated herein by reference.

8
9 **TECHNICAL FIELD**

10 This invention relates to golf club swing analyzers and golf swing
11 analysis methods.

12
13 **BACKGROUND OF THE INVENTION**

14 Electronic golf swing analyzers have been used to assist people
15 with monitoring characteristics of their individual golf swing. Some
16 configurations generally use some form of light detector (e.g.,
17 phototransistor, photo cell, etc.) as a sensor for use in swing analysis.
18 However, the prior art designs suffer from the same limitation wherein
19 they perform adequately indoors with a stationary overhead light source,
20 but fail to operate properly when utilized outdoors. More specifically,
21 measurements of conventional swing analyzers become erratic and
22 inaccurate in the presence of the moving sun during outdoor use.
23 These machines are not reliable when used outdoors.

1 Referring to Fig. 1, one conventional optoelectronic golf swing
2 analyzer configuration is shown. An array of light sensors 12 is
3 imbedded in a hitting platform 10 in reasonably close proximity to a
4 golf ball 11 to be struck by an approaching golf club 14. A lamp 13
5 is mounted in a fixed position above sensor array 12 to provide a
6 source of infrared light for sensor array 12.

7 As the clubhead of golf club 14 approaches golf ball 11, the light
8 is blocked from some of the sensors of array 12 and this condition is
9 subsequently detected. Sensor array 12 is arranged in a specific pattern
10 that allows detection of the position and timing of the clubhead of
11 club 14 in the impact area of golf ball 11. From this data, important
12 information about the golf swing can be calculated and displayed. For
13 example, clubhead path, clubface angle, clubhead speed, impact point of
14 ball upon the clubface, tempo or swing time, ball velocity and ball carry
15 are exemplary parameters which may be calculated and displayed to the
16 user.

17 The type of device illustrated in Fig. 1 functions properly when
18 used indoors with a fixed overhead light source, such as lamp 13.
19 However, when the device is used outdoors and especially in the sun,
20 several factors have a negative influence on performance which preclude
21 accurate detection of clubhead timing and position.

22 Fig. 2 shows a typical sensor circuit for a conventional
23 optoelectronic swing analyzer arrangement. The depicted circuit
24 comprises a light detector 21 coupled with a resistor 22 and comparator

1 circuit 23. A steady state source of light 20 from lamp 13 (not shown)
2 illuminates light detector 21 which provides a high signal output (+V)
3 due to the light current flowing through resistor 22. When the
4 clubhead passes over light detector 21, the light current is reduced and
5 the output signal goes to a logic low (0) state. The output signal is
6 routed to logic gate or comparator 23 which detects this change in
7 output signal from resistor 22. The change in the output signal
8 indicates the passage of the clubhead.

9 Referring to Fig. 3 - Fig. 5, problems typically experienced with
10 the utilization of such conventional devices in the outdoors is illustrated.
11 If the analyzer is exposed to the sun, device operation becomes erratic
12 inasmuch as sunlight contains more intense infrared energy than the
13 overhead lamp. Thus, sensors 21 tend to respond to the presence or
14 absence of sunlight.

15 Further, other sources of error can be attributed to the fact that
16 the sun is constantly moving such that the light source for the detectors
17 comes from many different directions depending upon the time of day.
18 A plurality of sensors 21 are sequentially labeled 1 thru 13 in Fig. 3 -
19 Fig. 5. The sun is directly overhead in the illustration of Fig. 3 and
20 plural light rays 30 therefrom radiate straight down casting a shadow 31
21 directly under the clubhead of club 14. Sensors 21 numbered 4 thru 8
22 are blocked from light 30 in Fig. 3.

23 The position of the sun in Fig. 4 is to the right of club 14 and
24 light rays 30 are angled from right to left in a downward direction

creating shadow 31 that lags the clubhead of club 14 (assuming the clubhead is moving from left to right in Fig. 4). Sensors 21 numbered 1 thru 6 are blocked from the sun in Fig. 4 although the position of the clubhead of club 14 with respect to sensors 21 is identical in Fig. 3 - Fig. 5.

The sun is to the left of club 14 in Fig. 5 with light rays 30 angled from left to right in a downward direction creating shadow 31 that leads clubhead 14 (again assuming movement of the club in a direction from left to right). Sensors 21 numbered 6 thru 12 are blocked from light 30 from the sun in this case.

Although clubhead 14 is in the same exact position in the above illustrations with respect to sensors 21, the actual sensors 21 that are blocked from the light source (e.g., the sun) change as the light source moves. This creates errors in measurement of clubhead position. Furthermore, any given sensor 21 is blocked from the light source at a different time during the swing as the sun moves across the sky. This creates errors in timing measurements.

The problem is further complicated by the fact that the intensity of the light seen by the sensors 21 also changes as the sun moves. The light is most intense when the sun is directly above sensors 21 as shown in Fig. 3, and least intense in the morning and evening hours corresponding to Fig. 4 and Fig. 5. Other sources of measurement errors include reflections of light from the leading edge of the clubhead and shadows cast by nearby objects across the array of sensors 21.

1 One way to reduce problems associated with the use of
2 conventional devices outdoors includes completely shading all sensors 21
3 of this type analyzer from sunlight so that only light from overhead
4 light 13 reaches the light detectors 21. Such could include using the
5 analyzer in a tent with the associated costs and inconvenience.

6 As is readily apparent, the above configurations prove problematic
7 in a prime desired application of the analyzer - use outdoors. Further,
8 the suggested solutions have associated drawbacks which reduce the
9 attractiveness or feasibility of utilizing the conventional devices outdoors.

10 Referring to Fig. 6 and Fig. 7, another technique used in some
11 conventional configurations to detect a clubhead is illustrated. An
12 emitter 34 is positioned to radiate a steady beam of light 35 in an
13 upward direction. When the clubhead of club 14 passes over light 35,
14 a portion of the light is reflected down and increases the light current
15 through a phototransistor 37 which produces a voltage response across
16 an associated resistor 38.

17 These circuit configurations will typically not operate properly in
18 direct sunlight because infrared energy emitted from the sun is much
19 more intense than that of emitter 34. Accordingly, any change in
20 phototransistor current caused by sunlight will overpower any small
21 change in current due to reflected light energy 35.

22 Some devices have been designed to use horizontal beams of light
23 energy in an effort to overcome problems caused by sunlight. The
24 emitters and detectors are housed in boxes that protect associated

1 sensors from direct sunlight. Such sensors are typically configured to
2 detect the moment a clubhead breaks a horizontal beam of light.
3 There are a number of patents that describe such devices, including
4 U.S. Patent No. 5,692,966, U.S. Patent No. 5,257,084, U.S. Patent No.
5 5,324,039 and U.S. Patent No. 5,087,047.

6 A significant drawback with these designs is that the devices are
7 usually restricted to calculating timing measurements of the moving
8 clubhead without providing position measurements. Therefore, such
9 devices are limited to measuring clubhead speed and tempo. Additional
10 important swing parameters such as clubhead path, clubface angle and
11 the impact point of the ball on the clubface require position
12 information of the clubhead.

13 Therefore, a need exists to provide a sensing system and
14 methodologies that overcome the limitations of the above-described
15 configurations, and produce accurate measurements both indoors and
16 outdoors, and during night or day.

17 **BRIEF DESCRIPTION OF THE DRAWINGS**

18
19 Preferred embodiments of the invention are described below with
20 reference to the following accompanying drawings.

21 Fig. 1 is an isometric view of a conventional swing analyzer
22 configuration.

23 Fig. 2 is a schematic diagram of sensor circuitry of the swing
24 analyzer shown in Fig. 1.

1 Fig. 3 - Fig. 5 are diagrammatic representations of the effects of
2 the sun when the swing analyzer of Fig. 1 is utilized outdoors.

3 Fig. 6 is an elevated side view depicting a golf club over a
4 sensor configuration of the swing analyzer of Fig. 1.

5 Fig. 7 is a schematic diagram of circuitry corresponding to Fig. 6.

6 Fig. 8 is an isometric view of a swing analyzer according to the
7 present invention.

8 Fig. 9 is an elevated side view of a golf club adjacent a sensor
9 configuration of the swing analyzer of Fig. 8.

10 Fig. 10 is a schematic diagram illustrating circuitry corresponding
11 to the swing analyzer of Fig. 9.

12 Fig. 11 is an elevated side view illustrating movement of a golf
13 club above the sensor configuration of Fig. 9.

14 Fig. 12 is a schematic diagram illustrating circuitry of an
15 exemplary sensor configuration.

16 Fig. 13 is a graph depicting voltage versus time corresponding to
17 movement of a golf club with respect to the sensor configuration of
18 Fig. 12.

19 Fig. 14 is a schematic diagram of one embodiment of a
20 discrimination circuit of the swing analyzer shown in Fig. 8.

21 Fig. 15a - Fig. 15f are graphs illustrating respective voltages versus
22 time at selected nodes within the discrimination circuit of Fig. 14.

23

24

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

This disclosure of the invention is submitted in furtherance of the constitutional purposes of the U.S. Patent Laws "to promote the progress of science and useful arts" (Article 1, Section 8).

According to one aspect of the present invention, a golf club swing analyzer comprises: a housing; a light emission device configured to emit reference light toward a location in the path of a golf club swung adjacent the housing; a light reception device supported by the housing and configured to receive reference light emitted from the light emission device and reflected from the swung golf club; and discrimination circuitry coupled with the light reception device and configured to distinguish the reflected reference light received from the light emission device from incidental light, the discrimination circuitry being further configured to generate an indication signal responsive to the reception of reflected reference light.

Another aspect of the present invention provides a golf club swing analyzer comprising: a housing; a light emission device configured to emit reference light in a substantially vertical direction toward a location in the path of a golf club swung adjacent the housing, the light emission device being further configured to emit the reference light in a plurality of pulses individually having a duration less than the duration of one of the rise time and fall time resulting from the swung golf club blocking incidental light from the light reception device; a light reception device supported by the housing and configured to

1 receive reference light emitted from the light emission device and
2 reflected from the swung golf club; and discrimination circuitry coupled
3 with the light reception device and configured to distinguish the
4 reflected reference light received from the light emission device from
5 incidental light including generating a timed pulse responsive to
6 reference light being received within the light reception device, the
7 timed pulse having a duration greater than the duration of the
8 reference light pulses and less than an individual one of the rise time
9 and fall time.

10 According to another aspect of the present invention, a golf swing
11 analysis method comprises: emitting reference light toward a location in
12 the path of a golf club swung adjacent the housing; receiving reference
13 light reflected from the swung golf club; receiving incidental light;
14 discriminating the reflected reference light and the incidental light
15 following the receivings; generating at least one indication signal
16 responsive to the discriminating.

17 The present invention provides a golf swing analyzer and golf
18 swing analysis method configured to overcome limitations of the prior
19 art devices. The swing analyzer according to the present invention
20 includes sensors which provide accurate measurements of a golf club
21 both indoors and outdoors and during night or day. The described
22 swing analyzer operates without the use of an overhead light source and
23 there is no need to shade the device from sunlight or other incidental
24 light, also referred to as environmental light. According to the

1 described embodiment, the depicted swing analyzer utilizes an electronic
2 circuit configured to reject sensor responses caused by changes in
3 illumination from incidental light including sunlight. As described in
4 detail below, the preferred swing analyzer configuration of the invention
5 utilizes a self-contained light source to create circuit responses. The
6 swing analyzer operates properly in any lighting environment from direct
7 sunlight to near total darkness. The disclosed swing analyzer
8 implements a sensing technique with improved convenience, usefulness,
9 accuracy and reliability of operation.

10 Referring to Fig. 8, one embodiment of a golf swing analyzer 40
11 according to the present invention is illustrated. The depicted golf
12 swing analyzer 40 includes a housing 42, such as a hitting platform.
13 In the illustrated embodiment, a tee 43 is coupled with housing 42 and
14 configured to receive a golf ball 44. A golf club 60 having a
15 clubhead 62 is swung adjacent housing 42 in the indicated direction to
16 provide analysis of a user's golf swing.

17 Housing 42 includes an upper surface 45 configured to face
18 upwardly away from the ground or other similar support surface upon
19 which golf swing analyzer 40 may be positioned. Tee 43 extends
20 upwardly from upper surface 45.

21 In the depicted configuration of the present invention, plural
22 sensor arrays 47, 48 are provided embedded within upper surface 45 of
23 housing 40. Individual sensor arrays 47, 48 comprise a plurality of
24

1 sensor configurations generally individually depicted with reference
2 numeral 49 in Fig. 8.

3 Sensor configurations 49 are provided in predefined positions upon
4 and/or within housing 42. More specifically, plural sensor arrays 47, 48
5 including sensors 49 are arranged in a configuration to provide
6 measurements of position and timing of clubhead 62 in the impact area
7 with golf ball 44. Such provides important information or characteristics
8 regarding a golf swing. Exemplary characteristics include clubhead path,
9 clubface angle, clubhead speed, impact point of ball on the clubface,
10 tempo or swing time, ball velocity, and ball carry. These parameters
11 can be calculated and displayed to the user.

12 Referring to Fig. 9, an exemplary embodiment of sensor
13 configuration 49 is illustrated. In particular, reflected light is used in
14 the described embodiment to provide desired measurements. Such
15 operation of reflecting reference light off a swung club 60 is described
16 with reference to Fig. 9. The depicted sensor configuration 49
17 comprises a light emission device 50 and a corresponding light reception
18 device 52 coupled with and supported by housing 42. In the described
19 embodiment, light emission device 50 is configured to emit reference
20 light 54 and light reception device 52 is configured to receive the
21 reference light reflected by clubhead 62.

22 In one configuration, light emission device 50 comprises an
23 infrared (IR) emitting diode configured to emit infrared light energy.
24

Device 50 has part designation SFH484 available from Siemens AG in one embodiment.

The preferred requirements for light detector or light reception device 52 include small size, capable of sensing high frequency pulses and capable of operating in direct sunlight without going into a condition of saturation. From many available light detector devices, a high frequency photodiode is utilized in the preferred embodiment of the invention. In particular, light reception device 52 comprises a photodiode sensitive to the infrared band and has part designation SFH203FA available from Siemens AG in the described embodiment. Alternatively, light reception device 52 can comprise a phototransistor. Other sensor configurations 49 are possible.

In typical use, a user swings golf club 60 having clubhead 62 adjacent housing 42 and sensor configurations 49. Preferably, a user swings club 60 such that clubhead 62 passes approximately 0.5 inches above surface 45 of housing 42.

According to the preferred embodiment, light emission device 50 is configured to emit reference light 54 in a substantially vertical direction. Emission and reception devices 50, 52 are configured to respectively radiate and detect vertical light beams in the described embodiment. Further, devices 50, 52 forming individual sensor configurations 49 may be positioned in an appropriate array similar to that shown in Fig. 8 in order to provide clubhead position measurements with respect to the golf ball or target line.

1 Light emission device 50 is configured to emit reference light 54
2 toward a location in the path of golf club 60 swung adjacent
3 housing 42. Such location can comprise the position of clubhead 62
4 shown in Fig. 9. During a swinging motion of club 60, clubhead 62
5 passes adjacent housing 42 and through the predefined location.
6 Clubhead 62 operates to reflect emitted reference light 54 when
7 positioned in the predefined location shown in Fig. 9.

8 Emission device 50 and reception device 52 are preferably
9 mounted side by side in close proximity such that reflected reference
10 light 54 is directed toward light reception device 52. Light reception
11 device 52 is configured to receive reference light 54 emitted from light
12 emission device 50 and reflected from clubhead 62 of the swung golf
13 club 60.

14 Referring to Fig. 10, a circuit diagram corresponding to the sensor
15 configuration 49 of Fig. 9 is illustrated. In particular, light emission
16 device 50 of sensor 49 is coupled with a pulse source or generator 56.
17 Light reception device 52 of sensor 49 is coupled with discrimination
18 circuitry 70.

19 Pulse source 56 applies a plurality of pulses at a predefined
20 frequency to light emission device 50. This causes emission of reference
21 light 54 at the frequency of the generated pulses. As described in
22 detail below, the pulses preferably comprise high frequency pulses having
23 a frequency in the range of 60 kHz or higher and a duty cycle of
24 approximately 50%. If clubhead 62 is provided in the predefined

1 location of Fig. 9, pulses of reference light 54 are reflected by
2 clubhead 62 and applied to light reception device 52. Such causes a
3 current to flow through light reception device 52 and permits detection
4 of club 60 at the predefined location shown in Fig. 9.

5 As previously mentioned, swing analyzer 40 is configured to
6 operate indoors as well as outdoors. Incidental light, such as sunlight
7 or incandescent light, is typically present in both indoors and outdoors
8 environments. Passage of clubhead 62 through the predefined location
9 above sensor configuration 49 temporarily blocks the passage of
10 incidental light to sensor configuration 49. Swing analyzer 40 is
11 configured to eliminate the effects of blocked incidental light upon
12 sensor configuration 49.

13 Referring to Fig. 11, operation of sensor configuration 49 is
14 described with reference to temporary blockage of incidental light
15 present within the operating environment. According to the described
16 embodiment, light reception device 52 includes an acceptance angle θ .
17 An exemplary acceptance angle θ of photodiode light reception
18 device 52 is approximately 16 degrees. A distance x is defined as the
19 distance clubhead 62 passes through the acceptance angle of light
20 reception device 52. Distance x is approximately 0.14 inches if
21 clubhead 62 is swung approximately 0.5 inches above surface 45 of
22 housing 40 and the acceptance angle θ is 16 degrees.

23 As clubhead 62 passes a distance x through the area defined by
24 angle θ , incidental light is blocked from light reception device 52.

1 Blockage of incidental light provided to light reception device 52
2 reduces the current flow through light reception device 52. However,
3 the blockage of incidental light is not instantaneous but gradually occurs
4 as clubhead 62 sweeps through distance x of the area defined by
5 angle θ . Thus, the current through light reception device 52 gradually
6 changes during passage of clubhead 62 over light reception device 52.

7 Referring to Fig. 12, an exemplary circuit 66 for illustrating the
8 gradual blockage of incidental light during the movement of clubhead 62
9 adjacent swing analyzer 40 is shown. Depicted circuit 66 comprises a
10 light sensitive device 68 coupled intermediate a voltage supply and a
11 resistor 69. In the illustrated configuration, light sensitive device 68
12 comprises a phototransistor. Device 68 can also comprise a photodiode.
13 A reference node V_0 is defined at the junction of device 68 and
14 resistor 69.

15 Referring to Fig. 13, a time chart corresponding to the change of
16 current flow through device 68 responsive to a change in incidental light
17 is shown. The depicted time chart illustrates the voltage at node V_0
18 and across resistor 69. Reduction of incidental light provided to
19 device 68 results in reduced current flow through device 68. As the
20 current through light emission device decreases over time, the output
21 voltage at node V_0 and across resistor 69 coupled with device 52 also
22 decreases.

23 If clubhead 62 moves at a maximum speed of 140 mph (2462
24 inches per second) across distance x , the output voltage at node V_0 will

1 have a fall time T_f of about 56 microseconds (μsec) as illustrated in
2 Fig. 13. According to one embodiment of the present invention, swing
3 analyzer 40 is configured to reject all voltage signals having fall times
4 (or rise times) of approximately 56 microseconds or more. Such
5 eliminates any effects of incidental light, such as the sun, upon the
6 accuracy of swing analyzer 40.

7 According to one embodiment of swing analyzer 40, providing a
8 sensor circuit that responds only to high frequency pulses effectively
9 eliminates the effects of incidental light. Accordingly, light emission
10 device 50 is preferably configured to provide high frequency pulses of
11 reference light 54 in one arrangement. Infrared emitters (IR emitters),
12 laser diodes and ultra-violet emitters are available exemplary devices that
13 provide this capability. Light emission device 50 comprises an IR
14 emitter in the preferred embodiment of this invention.

15 In other words, the time duration of the pulses comprising
16 reference light 54 is not critical as long as they are faster than 56 μs ,
17 or the fastest possible pulse generated by clubhead 62 interrupting
18 incidental light provided to light reception device 52. It is preferred
19 that the emitted reference light pulses 54 have an individual duration
20 less than the duration of one of the rise time and fall time resulting
21 from the swung golf club 60 blocking incidental light upon light
22 reception device 52.

23 Referring to Fig. 14, a simplified circuit diagram of an exemplary
24 discrimination circuit 70 is illustrated coupled with a corresponding

1 emitter-detector circuit 71 which includes sensor configuration 49 and
2 pulse source 56. Discrimination circuit 70 is further coupled with a
3 processing device 88 and display 89 in the described embodiment.

4 Discrimination circuit 70 is configured to distinguish reflected
5 reference light 54 from incidental light. In the described arrangement,
6 discrimination circuit 70 is configured to distinguish voltage signals
7 having fall (or rise) times of approximately 56 microseconds or more
8 from voltage signals having faster fall or rise times.

9 The depicted embodiment of discrimination circuit 70 comprises an
10 amplifier circuit 72, comparator circuit 73, and pulse discriminator
11 circuit 74. Amplifier circuit 72 is coupled with emitter-detector
12 circuit 71 and pulse discriminator circuit 74 is coupled with processing
13 device 88. Comparator circuit 73 couples amplifier circuit 72 with
14 discriminator circuit 74.

15 Referring to Fig. 15, a plurality of voltage waveforms 90-95 are
16 illustrated which correspond to voltages at a plurality of respective
17 nodes 80-85 shown in the circuit of Fig. 14. Waveform 90 corresponds
18 to the output voltage of pulse source 56 at node 80. Waveform 91
19 corresponds to the output voltage of light reception device 52 at
20 node 81. Waveform 92 corresponds to the output voltage of amplifier
21 circuit 72 at node 82. Waveform 93 corresponds to the output voltage
22 of comparator circuit 72 at node 83. Waveform 94 corresponds to the
23 output voltage of a one-shot multivibrator 75 within pulse discriminator
24

1 circuit 74 at node 84. Waveform 95 corresponds to the output of
2 pulse discriminator circuit 74 at node 85.

3 Referring to Fig. 14 and Fig. 15, pulse source 56 of emitter-
4 detector circuit 71 produces a train of 15 microsecond (μ s) pulses which
5 comprise an encoding signal. The frequency of the pulses is set by
6 resistor R_0 and capacitor C_0 .

7 The encoding signal drives transistor Q1 which, in turn, causes
8 emitter diode 50 to emit 15 μ s pulses of infrared light energy 54.
9 Resistor R_2 controls the maximum current through device 50 which
10 determines the intensity of the infrared pulses.

11 When an object (e.g., clubhead 62) passes over light emitting
12 device 50, the emitted infrared pulses comprising the reference light 54
13 are reflected and detected by device 52. The light current from
14 device 52 flows through resistor R_3 and develops a series of fast
15 voltage pulses shown as waveform 91. The signal comprising
16 waveform 91 is thereafter applied to and amplified within amplifier
17 circuit 72.

18 Amplifier circuit 72 in the preferred embodiment comprises two
19 high-speed operational amplifiers U_2 , U_3 . Amplifiers U_2 , U_3 individually
20 have part designation AD8032 and are available from Analog Devices,
21 Inc. in the described embodiment. The input voltage pulses of
22 waveform 91 are first amplified by circuit U_2 whose gain is determined
23 by resistor R_4 . The signal is then coupled to amplifier circuit U_3
24 through capacitor C_3 . The gain of this amplifier stage is determined

1 by resistors R_7 and R_8 . The voltage output of amplifier U_3 is
2 waveform 92 which is applied to comparator circuit 73.

3 The voltage output from amplifier circuit 72 varies in amplitude
4 depending on the amount of infrared energy reflected to device 52 as
5 illustrated by waveform 92. Comparator circuit 73 provides a fixed
6 trigger point for comparator U_4 which produces a constant output
7 voltage, as shown as voltage waveform 93, that swings from
8 approximately 0 volts (ground) to approximately $V+$ (the power supply
9 voltage of approximately 5 volts). Comparator U_4 has part designation
10 LM339 available from National Semiconductor Corporation in the
11 described embodiment. This output voltage represented by waveform 93
12 is constant over a wide range of levels of input voltage corresponding
13 to waveform 92. The comparator trigger point is set by resistors R_9 ,
14 R_{10} , R_{11} and capacitor C_4 .

15 When device 52 detects a change in light level, the output voltage
16 of comparator 73 (e.g., waveform 93) changes. The output voltage
17 signal from comparator circuit 73 is applied to one-shot (or monostable)
18 multivibrator 75 (also represented as component U_5 in Fig. 14). The
19 output of comparator circuit 73 is also applied to an input of a NAND
20 gate U_6 in pulse discriminator circuit 74. NAND gate U_6 comprises
21 a 74HC00 available from National Semiconductor Corporation in the
22 described embodiment. The illustrated one-shot multivibrator U_5 is
23 preferably a non-retriggerable type circuit.
24

1 In the absence of an input signal from device 52, the output
2 voltage of comparator circuit 73 is at a high level near V+ and the
3 voltage at node 84 is at a low level near 0 volts. The low level at
4 node 84 is applied to input 1 of NAND gate U₆ which holds the
5 output voltage at node 85 at a high level.

6 An increase in light current through reception device 52 causes
7 the voltage at node 83 to fall from a high level to a low level. The
8 low level at node 83 applied to input 2 of the NAND gate U₆
9 maintains the output voltage at node 85 at a high level. Also, the
10 high to low transition of the voltage at node 83 triggers the one-shot
11 multivibrator U₅ to produce a positive output pulse at node 84. The
12 time duration of the pulse should be less than 56 μ s (i.e., the fall or
13 rise time of blocked incidental light) and somewhat longer than 7.5 μ s
14 (i.e., one half the period of the input pulses produced by pulse
15 source 56).

16 In particular, multivibrator U₅ is preferably configured to generate
17 a timed pulse responsive to reference light being received within light
18 reception device 52. The timed pulse preferably has a duration greater
19 than the duration of a single reference light pulse and less than an
20 individual one of the rise time and fall time resulting from the swung
21 golf club blocking incidental light from light reception device 52. In
22 the described embodiment, a pulse width for the timed pulse from
23 multivibrator U₅ of about 12 μ s is selected.
24

1 The output pulse at node 84 appears at input 1 of NAND
2 gate U_6 , and if the voltage at node 83 at input 2 also goes positive
3 while input 1 is positive (within 12 μ s) an indication signal comprising
4 a negative going pulse will appear at node 85. An indication at
5 node 85 occurs responsive to reception of emitted reference light 54
6 within device 52. Since incidental light generated pulses are all greater
7 than approximately 56 μ s, such do not produce an output at node 85
8 and the circuit will respond only to the reflected infrared fast pulses 54
9 emitted from device 50. Responses to incidental light, including the
10 sun, are suppressed by discriminator circuit 74 of swing analyzer 40 of
11 the present invention.

12 The output indication at node 85 is applied to another one-shot
13 multivibrator U_7 in the illustrated configuration. Multivibrator U_7 can
14 have the same configuration as multivibrator U_5 . Multivibrators U_5 , U_7
15 have part designation CD4538 in the described embodiment available
16 from National Semiconductor Corporation. Multivibrator U_7 is
17 configured to output another indication signal responsive to the
18 reception of reflected reference light 54 within light reception device 52.
19 The output indication signal of multivibrator U_7 may be routed to
20 processing device 88 which can comprise a personal computer.
21 Device 88 can be configured to process the indication signal and display
22 results (i.e., at least one swing characteristic of the user's golf swing)
23 via user display 89 comprising a computer display in one embodiment.
24

Exemplary values of components of discrimination circuit 70 are found in the following Table 1. Other components can be utilized.

<u>Component</u>	<u>Value</u>
R ₀	1.5 kΩ
R ₁	470 Ω
R ₂	27 Ω
R ₃	2 kΩ
R ₄	3.3 kΩ
R ₅	10 kΩ
R ₆	10 kΩ
R ₇	33 Ω
R ₈	22 kΩ
R ₉	15 kΩ
R ₁₀	39 kΩ
R ₁₁	1 MΩ
R ₁₂	10 kΩ
R ₁₃	5.6 kΩ
R ₁₄	15 kΩ
C ₀	0.001 μF
C ₁	0.1 μF
C ₂	0.001 μF
C ₃	0.1 μF
C ₄	0.01 μF
C ₅	0.001 μF
C ₆	0.01 μF

The present disclosure relates to one possible embodiment of the invention. The circuit details of swing analyzer 40 can be changed while still performing the same or similar desired functions. For example, signal polarities can be reversed or substitute components utilized without changing the basic function of the sensor system.

In compliance with the statute, the invention has been described in language more or less specific as to structural and methodical

1 features. It is to be understood, however, that the invention is not
2 limited to the specific features shown and described, since the means
3 herein disclosed comprise preferred forms of putting the invention into
4 effect. The invention is, therefore, claimed in any of its forms or
5 modifications within the proper scope of the appended claims
6 appropriately interpreted in accordance with the doctrine of equivalents.
